

Waypoint AI Tool Disclosure

Team Nova | Tech Triathlon 2026 | Hackathon submission

We used OpenAI ChatGPT and Codex to assist with the development and documentation of Waypoint. This disclosure explains where AI contributed, how the team reviewed its output, and which responsibilities remained with us. It covers the Hackathon system build.

Tools and scope

ChatGPT and Codex supported requirements analysis, coding, debugging, validation planning, and documentation. Standard development tools included Git, TypeScript, ESLint, Vitest, Prisma, PostgreSQL, Docker, and browser developer tools. These supported implementation and verification rather than generative AI assistance.

Work assisted by AI

- Requirements and workflow review: interpreting and organizing the supplied challenge requirements, and comparing the implementation with the four role workflow and submission checklist.
- Implementation: drafting and refining TypeScript, React, CSS, Prisma schema, database migration, seed, and test code.
- Debugging: investigating build failures, database connections, responsive layouts, and workflow issues; proposing fixes for team review.
- Validation planning: suggesting test cases, validation checks, and operational edge cases.
- Documentation and cleanup: drafting and refining the README, architecture summary, data model summary, and this disclosure; identifying redundant working artifacts for final repository cleanup.

How we used and reviewed AI output

We supplied the competition brief, design references, project context, and relevant implementation material. AI tools proposed code, explanations, and documentation. We selected which suggestions to accept, modify, or reject, and reviewed retained work against the supplied brief, Designathon material, codebase, and applicable executable checks.

AI suggestions did not establish challenge requirements or business policy. The challenge documents, business scenario, brand definitions, and operational constraints were supplied inputs; they were not invented by the AI tools.

Human direction and responsibility

The team retained responsibility for product scope, priorities, visual direction, and final implementation decisions. We supplied the source material, assessed proposed changes, and reviewed the integrated user experience and workflow across roles.

Credentials, deployment access, submission links, and the final competition submission remained the team's responsibility. We also retained responsibility for the correctness, originality, security, and compliance of the submitted work.

The competition brief, project context, design references, and operational constraints were provided by people or competition materials. Human ownership of a decision does not mean that every supporting line of code or document was produced without AI assistance; the areas of assistance are disclosed above.

AI in the running application

Waypoint does not call a generative AI service at runtime. Allocation checks use deterministic application logic based on declared operational constraints. The running application does not send judge, account, order, or delivery data to ChatGPT or Codex.

This runtime statement is separate from the use of AI assistants during development, which is described in this disclosure.

Validation and known limitations

AI assisted changes were reviewed through source inspection and, where applicable, linting, automated tests, production builds, Docker health checks, and manual role walkthroughs. These checks were used to assess the integrated implementation rather than treating generated output as sufficient evidence of correctness.

Remaining scope differences from the Designathon are listed in the root README. Setup instructions, the judge walkthrough, and implementation context should be read alongside this disclosure. This statement does not claim that every suggested change received every type of check or that the system is free of defects.

Submission declaration

This disclosure records the assistance described for the Waypoint Hackathon build. The team remains accountable for the submitted system and documentation, including the accuracy of this statement. It does not make claims about AI use in a separate Datathon submission.
